

Exception Handling in boto3 scripts

- An exception is nothing but a run-time error that occurs during the execution of a Script
- We handle (catch) exceptions using try and except blocks instead of letting them crash the script
- In the context of Boto3 (the AWS SDK for Python), exceptions are raised when AWS service actions/operations/calls fail
- There are two types of Exceptions, they are:
 - Internal or Configuration Exceptions
 - Client-Side Exceptions
- Most of the exceptions in Boto3 are handled using `botocore.exceptions`
- `botocore` is the low-level core library that Boto3 is built on top of, and it defines the base exception classes used by Boto3
- Note:
 - Use `ClientError` to catch and inspect AWS service response failures as “except `ClientError` as `e`” and get Error Code & Message using `e.response`
