

Boto3 Waiters

- What are Waiters ?
 - Waiters are blocking concepts that polls AWS resources at regular intervals until a desired state is reached or until a timeout occurs
- We should use waiters whenever we perform create, update or delete operations on AWS resources that take time to transition between states
- We have waiters in both client and resource (few waiters and they internally uses client waiters only)
- **Some of the Waiter Examples:**
 - Wait until an EC2 Instance is stopped before modifying instance type
 - Wait until an EBS volume is available before attaching it to an instance
 - Wait until an RDS database is available before connecting
 - Wait until an AMI is ready before launching an EC2 instance
- There are two types of waiters in Boto3
- They are:
 - Default or Built-in waiters provided by Boto3
 - Custom Waiters
 - Custom waiters in Boto3 are an advanced skill that allow you to control polling behavior and enforce maximum time limits for resource readiness, instead of relying blindly on default behaviors

Steps to Develop Custom Waiters

🔧 Steps to Build Custom Waiters:

- Step-1: Identify What to Wait For
- Step-2: Write a Polling Loop
- Step-3: Add Timeout
